Covey Award (SB) Lecture Abstract IACAP 2014; July 2–4, Thessaloniki, Greece

We take hegemonic Bayesianism ( $\mathrm{HB}_{CogSci}$ ) in cognitive science to be the claim that human cognition consists of Bayesian processing, and take the in-AI-version of this claim ( $\mathrm{HB}_{AI}$ ) to be that the best route to reach human-level computing machines is to endow these machines with suitably tuned Bayesian processing. The sign of a mind infected with either or both of these views is that it outputs with disturbing frequency such sentences as

• "N in human cognition is just P[Bayesian]."

where N is an abstract noun and P[u] is an English phrase in which the word u appears; or, on the AI side, such sentences as

• "The best way to build a machine that can do N, is to use P[Bayesian]."

It's easy-peasy to refute both  $\mathrm{HB}_X$  claims. Path 1: Step  $1_1$ : For simplicity and economy, restrict N to be the kind of reasoning that humans routinely perform when doing formal logic and mathematics, and P to be 'Bayesian inference.' Step  $2_1$ : Observe now a rather ironic little problem: viz., Bayesian inference is insufficient to prove even the dirt-simple Bayes' Theorem. Step  $3_1$ : Observe that proving this theorem is to do (elementary) logic and mathematics. **QED** (If there are any hegemonic Bayesians in the Grecian room, they can be counted upon to be positively obdurate even in the face of the disproof just provided them, and to specifically spout the slogan that "Deduction [=N] here in human cognition is just a special case of Bayesian inference [=P]Bayesian] here]!" We shall explain in person why this protest is but vapor.)

A second refutation is available via Path 2: Step  $1_2$ : Observe that Bayesian inference is as a matter of mathematical fact based on some axiomatization  $\mathscr A$  of probability going back to Kolmogorov. Step  $2_2$ : Focus on the formal language  $\mathscr L$  on which  $\mathscr A$  is based. Step  $3_2$ : Show that  $\mathscr L$  is insufficiently expressive in the face of human logico-mathematical reasoning (which Leibniz,  $\approx$  three centuries before modern CogSci/AI arrived on the scene, apprehended when but a student). Step  $4_2$ : Accordingly, supplant  $\mathscr L$  with a more expressive  $\mathscr L'$ . We save the final two nails in the coffin for presentation in Thessaloniki, but are quite confident that readers will be able by non-Bayesian analogical reasoning to derive them from the final two steps in Path 1.

 $<sup>^1</sup>$ There is also of course the related neuro-claim (HB $_{Neuro}$ ): that the mechanisms in the brain corresponding to human cognition are fundamentally Bayesian in nature. A disproof of HB $_{Neuro}$  is saved for five minutes on another day. By the way, Bayesian doctrines other than the HB $_X$  treated herein have been decisively refuted; e.g., Bayesian epistemology by John Pollock, and Bayesian-reasoning-is-the-essence-of-scientific-argument by Clark Glymour.
